A pure implicitly parallel language does not need special directives, operators or functions to enable parallel execution, as opposed to explicit parallelism. Programming languages with implicit parallelism include Axum, BMDFM, HPF, Id, LabVIEW, MATLAB M-code, NESL, SaC, SISAL, ZPL, and pH.

In computer science, implicit parallelism is a characteristic of a programming language that allows a compiler or interpreter to automatically exploit the parallelism inherent to the computations expressed by some of the language's constructs. A pure implicitly parallel language does not need special directives, operators or functions to enable parallel execution, as opposed to explicit parallelism.

While this is done without making the entire language sequential, the state manipulation operations are still completely sequenced, so that one cannot have a parallel, state-manipulating program. In pH, on the other hand, despite the addition of M-structures, the overall programming style remains implicitly parallel unless otherwise specified.
